(Dated: April 23, 2013)

We present a direct connection between torus knots and Hopfions by finding stable and static solutions of the extended Faddeev-Skyrme model with a ferromagnetic potential term. (P, Q)–torus knots consisting of $|Q|$ sine-Gordon kink strings twisted P/Q times into the poloidal cycle along the toroidal cycle on a toroidal domain wall carry the Hopf charge PQ, which demonstrates that Hopfions can be further classified according to torus knot type.

arXiv:1304.6021v1 [hep-th] 22 Apr 2013

Around one and half centuries ago, Lord Kelvin proposed that atoms are made of vortex knots [1]. Although this theory was rejected, his research lead Tait to devise the celebrated knot theory in mathematics. Since then, knot theory has become an important subject in topology. One useful construction of knots is the torus knot, in which a braid group on strings on a torus is manipulated. Torus knots are characterized by two integers P and Q representing the number of string twists along the torus and the number of strings, respectively. Torus knots of vortices or line defects have been investigated broadly in physics [2]: fluid mechanics and plasma [3], helium superfluid [4], Bose-Einstein condensates of ultracold atoms [5], nonequilibrium systems [6], colloids [7], optics [8], excited media [9], quantum chromodynamics [10], and classical field theory [11].

On the other hand, in high-energy physics, a field theoretical model admitting knot-like solitons, namely, the Faddeev-Skyrme (FS) model [12], which is an $O(3)$ sigma model with four derivative (Skyrme) terms, was proposed. Stable (un)knots were first constructed in References [13, 14]. More generally, this model admits solitons having a topological charge, *i.e.*, a Hopf charge classified by the homotopy group $\pi_3(S^2) \simeq \mathbf{Z}$, which are referred to as Hopfions [15, 16]. (Un)stable Hopfions have also been investigated in various physical systems such as exotic superconductors [17], ferromagnets [18], and Bose-Einstein condensates [19]. Stable Hopfions with higher Hopf charges in the FS model were numerically constructed [15], and in particular the first nontrivial knot structure appears in Hopfions with the Hopf charge 7 [20, 21]. Knot structures were also found in Hopfions with potential terms [22–24]. While it was conjectured [15] that all torus knots can be constructed as Hopfions, a precise connection between Hopfions and knots remains unclear.

In our previous paper [25], we considered the Faddeev-Skyrme model with a ferromagnetic potential term, that is, a potential term quadratic in the field [26, 27] admitting two discrete vacua and a domain wall with a $U(1)$ modulus interpolating between them [27–29]. Hopfions can be constructed as twisted closed lump (baby Skyrmion) strings [13, 30], which are characterized by the number of twists P and the lump (baby Skyrmion) charge Q, which takes a value in $\pi_2(S^2) \simeq \mathbf{Z}$ of the constituent lumps. We found that the Hopfions are all in a toroidal shape, that is, toroidal domain walls, and that the $U(1)$ modulus of the domain wall is twisted P and Q times along the toroidal and poloidal cycles of the torus, respectively. The Hopf charge C was found to be the product $C = PQ$, and consequently the Hopfions with the Hopf charge C can be further classified according to two topological charges P and Q. We explicitly constructed stable (P, Q) Hopfion solutions with P and Q from one to three, resulting in the Hopf charges, 1, 2, 3, 4, 6, 9. An immediate question arises. Aren't there any knot structures for Hopfions with higher Hopf charges in this model, unlike the conventional Hopfions?

In this Letter, we find a direct connection between Hopfions and torus knots in a different manner from [15]. We show this by deforming the ferromagnetic Faddeev-Skyrme model [25, 27], with adding a further potential term linear in the field, considered in the original baby Skyrme model [31]. The total potential is well known in condensed matter physics as ferromagnets with two easy axes. With this potential, we previously found in the case of $d = 2 + 1$ dimensions that $|Q|$ sine-Gordon kinks appear on a domain wall [32] or a domain wall ring [33] with the lump charge Q. For the (P, Q) Hopfions, $|Q|$ sine-Gordon kink strings appear on the toroidal domain wall, which are twisted P/Q times into the poloidal cycle along the toroidal cycle with forming (P, Q)–torus knots. We numerically construct stable Hopfions in this model and find that the Hopf charge C is the product PQ of (P, Q)–torus knots. In other words, Hopfions with the Hopf charge C can be further classified according to the torus knot type.

We start with the Lagrangian density of the FS model:

$$\begin{aligned} \mathcal{L} &= \frac{1}{2}\partial_\mu \boldsymbol{n} \cdot \partial^\mu \boldsymbol{n} - \kappa F^{\mu\nu} F_{\mu\nu} - V(\boldsymbol{n}), \\ \boldsymbol{n} \cdot \boldsymbol{n} &= 1, \quad F_{\mu\nu} = \boldsymbol{n} \cdot (\partial_\mu \boldsymbol{n} \times \partial_\nu \boldsymbol{n}), \end{aligned} \tag{1}$$

where a unit three vector $\boldsymbol{n} = (n_1(x), n_2(x), n_3(x))$ of scalar fields is characterized as a point in the S^2 tar-

get space. In the original FS model with no potential, $V(\boldsymbol{n}) = 0$, three-dimensional Hopfion structures are stabilized in addition to the vacuum state. Next, we introduce the potential:

$$V(\boldsymbol{n}) = V_1(\boldsymbol{n}) + V_2(\boldsymbol{n}),$$
$$V_1(\boldsymbol{n}) = m^2(1 - n_3)(1 + n_3), \quad V_2(\boldsymbol{n}) = -\beta^2 n_1. \tag{2}$$

In the context of the baby Skyrme model in $d = 2 + 1$, only V_2 [31] or V_1 [26, 29] was considered. Here, we consider both terms in the regime $m \gg \beta > 0$ [32, 33]. This potential is known in ferromagnets with two easy axes. The potential V_1 allows two discrete vacua $n_3 = \pm 1$ and a domain wall interpolating between the vacua. $V_2(\boldsymbol{n})$ slightly shifts these vacua to $\mathbf{n} = (-\beta^2/2m, 0, \pm\sqrt{1 - \beta^4/4m^2})$, but this shift is negligible in the regime of $\beta \ll m$. It is, however, important for the domain wall solution. Inside the domain wall where $n_3 = 0$, $\boldsymbol{n}$ takes a value in S^1 within the n_1–n_2 plane, and $V_2(\boldsymbol{n})$ chooses $n_1 = 1$ as the most stable state inside the domain wall. In addition to the uniform $n_1 = 1$ solution on the domain wall, there also exists a sine-Gordon kink soliton solution constrained on the domain wall, where $\boldsymbol{n}$ in S^1 is wound from one $n_1 = 1$ point to the other $n_1 = 1$ point through the $n_1 = -1$ point in the n_1–n_2 plane. In the $(3 + 1)$–dimensional space, the kink soliton is a $(1 + 1)$–dimensional string on the $(2 + 1)$–dimensional domain wall world-volume [32].

Here, we briefly recall the Hopfion structures in the original FS model without the potential term, starting from the baby Skyrmion (lump) string in the FS model. Baby Skyrmions can be constructed by mapping the two-dimensional space at the fixed boundary to the S^2 target space for $\boldsymbol{n}$, as shown in Fig. 1(a). Figures 1(b)–(e) show typical spatial configurations of $\boldsymbol{n}$ for baby Skyrmions. For all of the baby Skyrmions shown in these figures, the states at the center and the boundary are fixed to $n_3 = 1$ and $n_3 = -1$, respectively. Differences between these figures can be found in the configurations in the gray colored annuli areas, where $\boldsymbol{n}$ is twisted once in the clockwise direction for Figs. 1(b) and 1(c), once in the anticlockwise direction for Fig. 1(d), and twice in the clockwise direction for Fig. 1(e) within the n_1–n_2 plane along the annulus. This number of twists counts the number of baby Skyrmions and is equivalent to the topological lump (baby Skyrmion) charge

$$Q = \frac{1}{8\pi}\int d^2x\, \epsilon^{\mu\nu} F_{\mu\nu}. \tag{3}$$

The charge Q is $+1$ in Figs. 1(b) and 1(c), -1 in Fig. 1(d), and $+2$ in Fig. 1(e). Baby Skyrmions, as shown in Figs. 1(b) and 1(c) can be continuously transformed by twisting $\boldsymbol{n}$ around the n_3 direction, because these Skyrmions have the same topological charges Q.

Next, we consider three-dimensional structures constructed from baby Skyrmions. The simplest and nontrivial one is the twisted baby Skyrmion strings shown in Fig. 2. There are sequences of baby Skyrmions along one
FIG. 1. Examples of baby Skyrmion structure. (a) S^2 target space of $\boldsymbol{n}$. $n_3 = 1$ (north pole) and $n_3 = -1$ (south pole) are denoted by $\odot$ and $\otimes$, respectively. Directions on the equator ($n_3 = 0$) are denoted by arrows: $(n_1, n_2) = (1, 0), (-1, 0), (0, 1)$, and $(0, -1)$ for right, left, up, and down arrows, respectively. (b)–(e) Spatial configurations of $\boldsymbol{n}$ for baby Skyrmions. The gray shaded annuli denote regions in which $n_3 \sim 0$. The topological charges defined in Eq. (3) of baby Skyrmions in (b)[(c)], (d), and (e) are $+1$, -1, and $+2$, respectively.

direction (the z–axis) in real space, and each slice is made of baby Skyrmions with the lump charges $Q = 1$ and $Q = 2$ in Fig. 2(a) and 2(b), respectively. The number of twists P in a segment of the twisted baby Skyrmion string is defined as the rotation angle $2\pi P$ of $\boldsymbol{n}$ in the n_1–n_2 plane in the target space from the bottom baby Skyrmion to the top baby Skyrmion [$P = 1$ for both Figs. 2(a) and 2(b)]. In the figures, we further show the loci of $n_1 = -1$, which become kink soliton strings on a cylindrical domain wall when $V(\boldsymbol{n}) \neq 0$. The locus of $n_1 = -1$ is rotated clockwise along the axis by 2π from the bottom to the top in Fig. 2(a), and each of two loci of $n_1 = -1$ is rotated by π in Fig. 2(b). In general, when a twisted baby Skyrmion string of the lump charge Q has P twists, there exit Q loci of $n_1 = -1$ rotated clockwise along the axis by $2\pi P/Q$.

Next, we look at Hopfions. Hopfions can be constructed as twisted closed baby Skyrmion strings by joining the tops and bottoms of twisted baby Skyrmion strings [13, 27, 30], as shown in Fig. 3. In baby Skyrmion rings, the surface defined by $n_3 = 0$ is in the form of a torus dividing the region of $n_3 = \pm 1$. On any section of the torus in a plane containing the z–axis, there is a pair of a baby Skyrmions with charge $Q (> 0)$ and an anti-baby Skyrmion with charge $-Q$. In Fig. 3(a), the number of twists is $P = 0$ for the constituent baby Skyrmion, and the configuration of $\boldsymbol{n}$ does not change along the ring. In Fig. 3(b), on the other hand, $\boldsymbol{n}$ is rotated by 2π in the n_1–n_2 plane in the target space along the ring with the number of twists $P = 1$. In general, baby Skyrmion rings can be characterized by the topological lump charge Q of
FIG. 2. Twisted baby Skyrmion string. The gray $n_3 = 0$ surfaces have cylindrical structures that separate the regions of $\odot$ and $\otimes$. Along the cylinders, there are sequences of baby Skyrmions with the charges of (a) $Q = 1$ and (b) $Q = 2$. From the bottom baby Skyrmion to the top baby Skyrmion, $\boldsymbol{n}$ rotates by $2\pi P$ ($P = 1$) in the n_1–n_2 plane, defining the number of twists P. The red and green lines indicate the locus of the $n_1 = -1$ state along the cylinder.

the constituent baby Skyrmions and the number of twists P along the ring. The Hopf charge C of $\pi_3(S^2) \simeq \mathbf{Z}$ defined by

$$C = \frac{1}{4\pi^2}\int d^3x\, \epsilon^{\mu\nu\rho}F_{\mu\nu}A_\rho, \quad A_\mu = \frac{\epsilon_{ijk}n_i\partial_\mu n_j}{3(1+n_k)} \tag{4}$$

is equivalent to the product PQ of the number of twists P and the constituent lump charge Q. To show this, we promote configurations with the target space S^2 to those with S^3 by the Hopf map. We introduce two complex scalar fields $\phi^T = (\phi_1, \phi_2)$ with the constraint of $|\phi_1|^2 + |\phi_2|^2 = 1$ which parametrizes ϕ by $S^3 \simeq SU(2)$. The three-vector scalar fields n_i can be written by the Hopf map

$$n_i = \phi^\dagger\sigma_i\phi, \quad (i = 1, 2, 3) \tag{5}$$

with the Pauli matrices σ_i. We next consider an ansatz

$$\begin{aligned} \phi &= \left(\cos R e^{-iP\phi} \ \ \sin R e^{iQ\Theta}\right), \\ R &= \cos^{-1}\{\sin f(r)\sin\theta\}, \\ \Theta &= -\tan^{-1}\left\{\frac{\sin f(r)\cos\theta}{-\cos f(r)}\right\} \end{aligned} \tag{6}$$
FIG. 3. Untwisted (a) and twisted (b) baby Skyrmion rings. The gray $n_3 = 0$ surfaces have torus structures that separate the regions of $\odot$ and $\otimes$. As the baby Skyrmion ring is rotated along the z–axis with from 0 to 2π, $\boldsymbol{n}$ on the torus does not twist in (a) and twists by 2π in (b). (c) Deformed twisted baby Skyrmion ring with $V(\boldsymbol{n}) \neq 0$. When $V(\boldsymbol{n})$ is switched on, the $n_1 = 1$ ($\rightarrow$) state on the gray toroidal domain wall is stabilized, which makes the $n_1 = -1$ ($\leftarrow$) state the kink soliton string constrained on the toroidal domain wall. The thick line indicates the position of the kink soliton.

with the polar coordinate (r, θ, ϕ). Here, a monotonically increasing function $f(r)$ satisfies the boundary condition

$$f(r \to 0) \to 0, \quad f(r \to \infty) \to \pi. \tag{7}$$

From the Hopf map in Eq. (5), we have

$$\begin{aligned} \boldsymbol{n} &= \left(\sin(2R)\cos\Phi \ \ \sin(2R)\sin\Phi \ \ \cos(2R)\right), \\ \Phi &= P\phi + Q\Theta. \end{aligned} \tag{8}$$

The configuration given in Eq. (8) is isomorphic to a torus knot with (P, Q) and its Hopf charge C can be obtained through the Hopf map in Eq. (5) from the Skyrme charge
FIG. 4. Toroidal domain wall (transparent green surface) and kink soliton strings (blue, red, and purple surfaces). The Hopf charge $C(=P)$ is 1 in (a)–(c), 2 in (d)–(f), and 3 in (g)–(i). The topological charge Q of the underlying lump is 1 in (a), (d), and (g), 2 in (b), (e), and (f), and 3 in (c), (f), and (i). The green surface is the isosurface of $n_3 = 0$. The blue, red, and purple surfaces are isosurfaces of $n_1 = -0.97$. We use a numerical box of unity in size that satisfies the Neumann boundary condition. We fix $\beta^2/m^2 = 0.1$ in all cases, and $\kappa/m^2 = 2.50 \times 10^{-6}$ in (a), (d), and (g), $\kappa/m^2 = 1.25 \times 10^{-6}$ in (b), (e), and (h), and $\kappa/m^2 = 6.25 \times 10^{-7}$ in (c), (f), and (i). In (e) and (i), different rings of kink soliton strings are shown by different colors.

$\pi_3(S^3) \simeq \mathbf{Z}$ of the fields ϕ in Eq. (6):

$$\begin{aligned} C &:= \frac{1}{2\pi^2}\int d^3x\, \epsilon^{abcd} s_a \partial_1 s_b \partial_2 s_c \partial_3 s_d \\ &= \frac{PQ}{\pi}\int_0^\infty dr\, \frac{d}{dr}\left\{f(r) - \sin f(r)\cos f(r)\right\} \\ &= PQ, \end{aligned} \tag{9}$$

with $\phi_1 = s_1 + is_2$ and $\phi_2 = s_3 + is_4$ $(a, b, c, d = 1, 2, 3, 4)$.

We now consider the potential term $V(\boldsymbol{n})$, which allows the vacua $n_3 \sim \pm 1$. For baby Skyrmions in $d = 2+1$, rings defined by $n_3 = 0$ become domain wall rings by the potential V_1. Furthermore, on the domain wall rings, the points of $n_1 = 1$ are stabilized and the points of $n_1 = -1$ become sine-Gordon solitons by the potential V_2. As a result, $|Q|$ sine-Gordon solitons appear on domain wall rings as baby Skyrmions with the lump charge Q in $d = 2+1$ [33]. For the Hopfions in $d = 3+1$, the toroidal surface defined by $n_3 = 0$ becomes a domain wall separating the two vacua $n_3 = \pm 1$, as shown in Fig. 3(c). Furthermore, $|Q|$ sine-Gordon soliton strings appear on the toroidal domain wall. Along the longitude of the torus of the domain wall, the kink soliton strings are rotated by $2\pi P/Q$, forming a (P, Q)–torus knot [34]. Therefore, the Hopfions with the charge $C(= PQ)$ in the original FS model correspond to (P, Q)–torus knots of the kink soliton strings on the toroidal domain wall in the FS model with $V(\boldsymbol{n}) \neq 0$. In other words, Hopfions are

further classified into topologically distinct (P, Q) torus knots with fixed $C = PQ$.

We numerically construct solutions of (P, Q)–torus knots by solving the Euler-Lagrange equation

$$\frac{\delta \mathcal{L}}{\delta \boldsymbol{n}} = \frac{\partial \mathcal{L}}{\partial \boldsymbol{n}} - \partial_\mu \frac{\partial \mathcal{L}}{\partial(\partial_\mu \boldsymbol{n})} = 0 \tag{10}$$

in the relaxation method. We introduce a relaxation time τ and the dependence of $\boldsymbol{n}$ on τ, and calculate the large-τ behavior for the equation:

$$\frac{\partial \boldsymbol{n}}{\partial \tau} = -\frac{\delta \mathcal{L}}{\delta \boldsymbol{n}}. \tag{11}$$

The initial configurations of $\boldsymbol{n}$ at $\tau = 0$ are given by Eq. (8), the configuration of which is isomorphic to a Hopfion with the charge $C = PQ$. Furthermore, in this configuration, the isosurface of $n_3 = 0$ takes a torus configuration, and loci of $n_1 = -1$ on the torus take the form of a (P, Q)–torus knot. As a result, we can obtain the solution for the (P, Q)–torus knot of kink solitons on the toroidal domain wall.

Figures 4(a)–(c) shows three different solutions with $P = 1$. The kink soliton strings form $(P, Q) = (1, 1)$, $(1, 2)$, and $(1, 3)$–torus knots in Figs. 4(a), (b), and (c), respectively, depending on the lump charge Q of the constituent lumps. All torus knots in these figures are topologically equivalent to the trivial knot. Figures 4(d)–(f) and 4(g)–(i) show solutions with $P = 2$ and $P = 3$, respectively. The kink soliton strings form $(2, 1)$, $(2, 2)$, $(2, 3)$, $(3, 1)$, $(3, 2)$, and $(3, 3)$–torus knots in Figs. 4(d), (e), (f), (g), (h), and (i), respectively. These knots are topologically equivalent to the trivial knot, the Hopf link, the trefoil knot, the trivial knot, the trefoil knot, and the link of three rings, a knot in which any pair of two strings makes the Hopf link, respectively.

All configurations shown in Fig. 4 are located at stationary and minimal points of the Lagrangian $L = \int d^3x\, \mathcal{L}$. In the original FS model without the potential term, different states with the same Hopf charge C are topologically equivalent and can be continuously deformed to each other under continuous changes of $\boldsymbol{n}$. In the case with $V(\boldsymbol{n}) \neq 0$, configurations with different sets of (P, Q) for torus knots of soliton strings are topologically distinct due to energy barriers between the knots, even when they have the same Hopf charge C. Therefore, the configurations can be classified by the two integers (P, Q) for torus knots rather than the Hopf charge C. All independent (P, Q) Hopfions are stable, topologically distinct and energetically separated by the potential barrier even for the same Hopf number $C = PQ$.

In conclusion, we have investigated the extended FS model with the potential term given in Eq. (2). In this model, the Hopfions in the original FS model can be expressed as the (P, Q)–torus knots of kink soliton strings of $n_1 = -1$ on the toroidal domain walls defined by $n_3 = 0$ interpolating between the two vacua $n_3 = \pm 1$. The toroidal domain walls are constructed as twisted rings of constituent lumps, and the two integers P and Q for the torus knots of kink soliton strings are the number of twists of $\boldsymbol{n}$ along the ring and the topological lump charge of the constituent lumps, respectively. The product PQ of the number of twists P and the constituent lump charge Q is equivalent to the Hopf charge C defined in Eq. (4). The Hopfions with the Hopf charge C are further classified according to the different types of (P, Q) torus knots with fixed $C = PQ$. All of them are stable, topological distinct, and energetically separated by the potential barrier.

We would like to thank the organizers of the "Quantized Flux in Tightly Knotted and Linked Systems" conference held December 3 to 7, 2012 at Isaac Newton Institute for Mathematical Sciences, where the present study was initiated. The present study was supported in part by Grants-in-Aid for Scientific Research (Grants No. 22740219 (M. K.) and No. 23740198 and 25400268 (M. N.)) and the M. N. was also supported by a Grant-in-Aid for Scientific Research on Innovative Areas ("Topological Quantum Phenomena") (No. 23103515 and 25103720) from the Ministry of Education, Culture, Sports, Science and Technology (MEXT) of Japan.

[34] Exactly speaking, P and Q should be coprime for the torus knot to be the exact *knot* comprising the only one closed string. If P and Q are not coprime, the torus knot becomes the link of more than two closed strings, *i.e.*, *torus link*. In this Letter, however, we use the term of the torus knot for both the exact torus knots and the torus links.
